PIOX S721

Process analysis and flow measurement with ultrasound

Non-invasive clamp-on ultrasonic measuring system for continuous monitoring of concentration, density or other process-relevant fluid properties

Features

- Time measurement for the accurate and repeatable determination of concentration, density and density-related physical quantities
- Reliable, maintenance-free and repeatable drift-free measurement
- High measurement accuracy even at very low as well as very high flow rates and independent of the flow direction (bidirectional)
- Installation and start-up do not require any pipe work nor any process interruptions
- Non-invasive: no fluid contact, no need of special materials, ideal for aggressive, toxic or abrasive fluids
- Bidirectional communication and support of common bus technologies (Profibus PA, Foundation Fieldbus, HART, Modbus, BACnet, M-Bus)
- Advanced self-diagnosis and possibilities for event-based triggering of data recording for the supervision and control of critical processes
- Transmitter and transducers for use in hazardous areas are available
- Transmitter and transducers are separately calibrated (traceable to national standards)
- Transducers available for a wide range of inner pipe diameters and fluid temperatures

Applications

For a wide range of fluids, e.g. H_2SO_4 , HF, HCl, HNO_3 , sugar solution (Brix), brine in:

- Chemical industry
- Petrochemical industry
- Oil and gas industry
- Pharmaceutical industry
- Semiconductor industry
- Mechanical and electrical industries
- Food industry

Function

Measurement principle

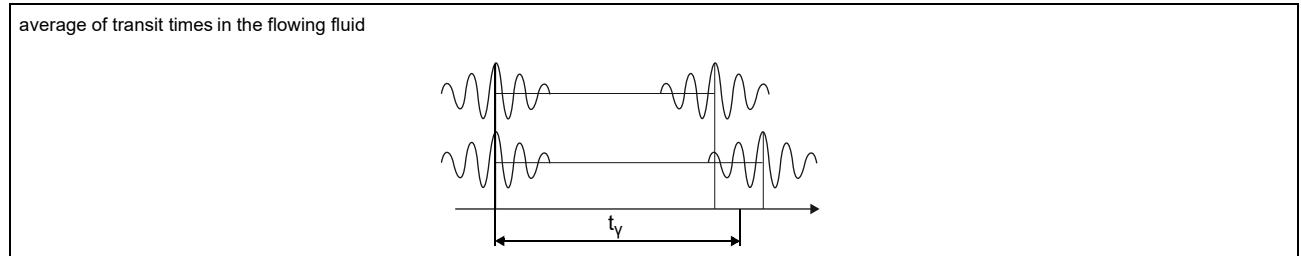

The transducers are mounted on the pipe which is completely filled with the fluid. The ultrasonic signals are emitted alternately by a transducer and received by the other. The physical quantities are determined from the transit times of the ultrasonic signals.

The transmitter determines physical quantities for analysis by using the transit time measurement and physical quantities for flow by means of the transit time difference principle.

Transit time measurement

All physical quantities for analysis are determined from the sound speed. The sound speed is calculated from the average of both ultrasonic signals in the fluid. By using the average, the sound speed is independent of the flow velocity of the fluid.

Calculation of sound speed

The sound speed is the quotient of the path of the ultrasonic signal in the fluid and transit time. The transit time is calculated as average of the transit times of both transducer signals in the fluid, corrected by the transit time in the transducer and in the pipe wall.

$$c_y = \frac{l_y}{t_y}$$

$$t_y = \frac{t_1 + t_2}{2}$$

where

c_y - sound speed in the fluid

l_y - sound path in the fluid

t_y - average of transit times in the fluid

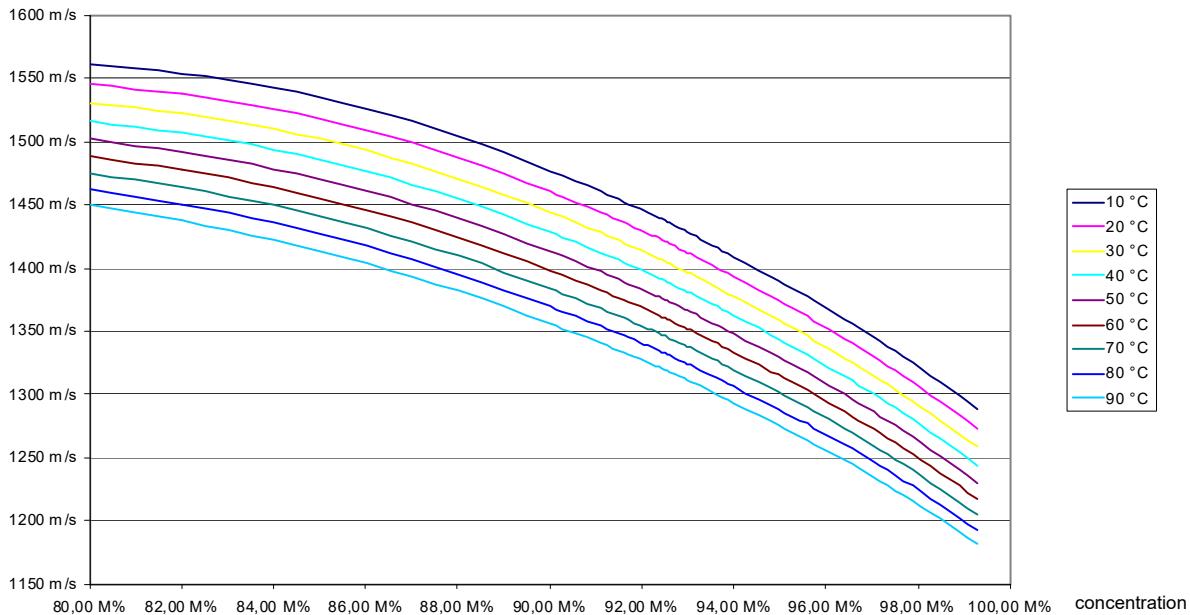

t_1, t_2 - transit time in the fluid

A field calibration is recommended to reduce the influence of the pipe parameters on the accuracy of the measurement.

Further physical quantities, e.g. concentration, density, degree of conversion, can be calculated in dependence on the measured sound speed and fluid temperature in the transmitter. This requires a set of characteristic curves where physical quantity, sound speed and fluid temperature are correlated. The characteristic curves can be prepared by FLEXIM if required.

Example of the dependence of the sound speed of sulfuric acid on concentration and temperature

sound speed

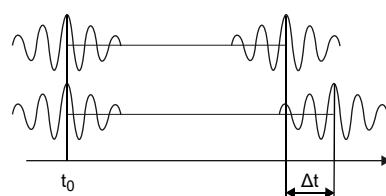

Transit time difference principle

As the fluid where the ultrasound propagates is flowing, the transit time of the ultrasonic signal in flow direction is shorter than the one against the flow direction.

The transit time difference Δt is measured and allows the flowmeter to determine the average flow velocity along the propagation path of the ultrasonic signals. A flow profile correction is then performed in order to obtain the area averaged flow velocity, which is proportional to the volumetric flow rate.

The integrated microprocessors control the entire measuring cycle. The received ultrasonic signals are checked for measurement usability and evaluated for their reliability. Noise signals are eliminated.

Transit time difference Δt

Calculation of volumetric flow rate

$$\dot{V} = k_{Re} \cdot A \cdot k_a \cdot \frac{\Delta t}{2 \cdot t_y}$$

where

- \dot{V} - volumetric flow rate
- k_{Re} - fluid mechanics calibration factor
- A - cross-sectional pipe area
- k_a - acoustical calibration factor
- Δt - transit time difference
- t_y - average of transit times in the fluid

Calculation of mass flow rate

The operating density of the fluid is calculated as the function of concentration and temperature of the fluid:

$$\rho = f(K, T)$$

The mass flow rate is calculated from the operating density and the volumetric flow rate:

$$\dot{m} = \rho \cdot \dot{V}$$

where

ρ - operating density

K - concentration

T - temperature

\dot{m} - mass flow rate

\dot{V} - volumetric flow rate

Number of sound paths

The number of sound paths is the number of transits of the ultrasonic signal through the fluid in the pipe. Depending on the number of sound paths, the following methods of installation exist:

- **reflection arrangement**

The number of sound paths is even. The transducers are mounted on the same side of the pipe. Correct positioning of the transducers is easy.

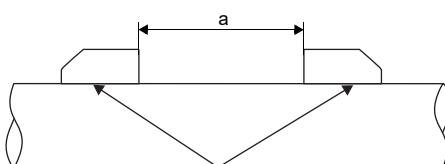

- **diagonal arrangement**

The number of sound paths is odd. The transducers are mounted on opposite sides of the pipe. In the case of a high signal attenuation by the fluid, pipe and coatings, diagonal arrangement with 1 sound path will be used.

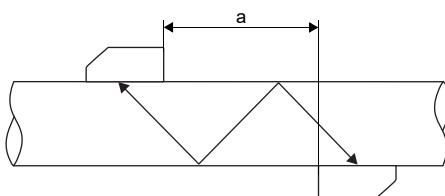

The preferred method of installation depends on the application. While increasing the number of sound paths increases the accuracy of the measurement, signal attenuation increases as well. The optimum number of sound paths for the parameters of the application will be determined automatically by the transmitter.

As the transducers can be mounted with the transducer mounting fixture in reflection arrangement or diagonal arrangement, the number of sound paths can be adjusted optimally for the application.

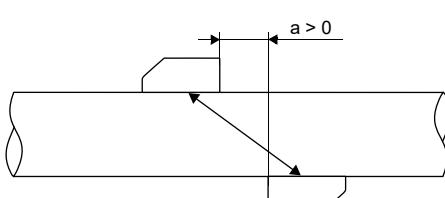

Reflection arrangement, number of sound paths: 2

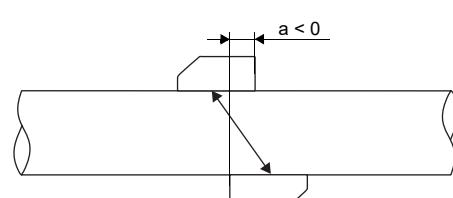

Diagonal arrangement, number of sound paths: 3

Diagonal arrangement, number of sound paths: 1

Diagonal arrangement, number of sound paths: 1, negative transducer distance

a - transducer distance
